

Datatypes

.NET

In computer science and computer programming, a data **type** or simple **type** is an attribute of data which tells the compiler or interpreter how the programmer intends to use the data.

Primitive Types in C# vs Java

https://medium.com/omarelgabrys-blog/primitive-data-types-in-c-vs-java-5b8a597eef05#:~:text=https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/built-in-types

Typically, the most familiar <u>primitive data types</u> are:

int, object, short, float, double, char, bool. These are called primitive because they are the types used to build other, more complex, data types.

In C#, what are considered primitive data types in other languages are actually objects. When you write:

- •int foo = 10;
- •string myString = "This is a string";

The variables foo and myString are Objects. They have helper functions built into C# to manipulate the data. C# is Strongly Typed. The compiler must know the type to be able to supply the helper functions.

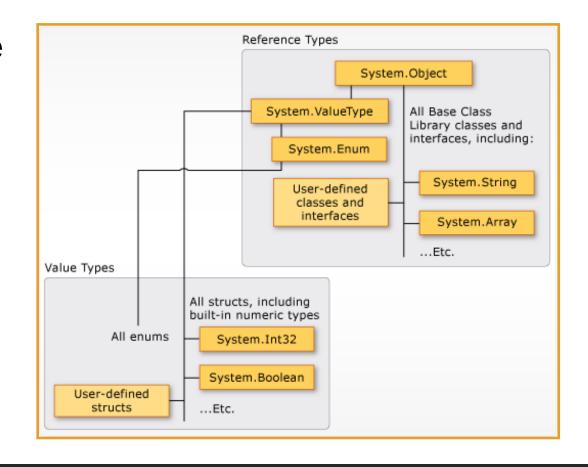

C# Datatypes Structure

https://docs.microsoft.com/en-us/dotnet/csharp/programming-guide/types/

All data types inherit from the base Class **Object**.

When an *int* is declared, you are declaring:

- an instance of the struct (an object) of type 'int',
- which inherits from System.ValueType,
- which itself inherits from System.Object

DataTypes

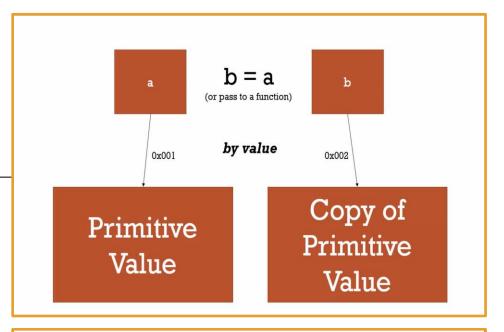

https://docs.microsoft.com/en-us/dotnet/csharp/tour-of-csharp/types-and-variables

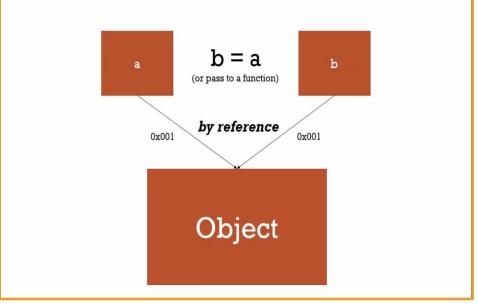

Value *types*:

- These are the built-in data types:
 - char, int, bool, float,
 - and user-defined *types* declared with *struct*.
 - Variables of *value* types directly contain their data on the *stack*.

Reference types:

- Class, Interface, array and delegate types contain other types.
- Variables of reference types do not contain an instance of the type, but merely a reference to an instance stored on the heap.

Value Types – Integral

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/integral-numeric-types

Integral numeric types represent integer numbers. All integral numeric types are value types. They are also simple types and can be initialized with <u>literals</u>.

Signed Integral	Ranges
Sbyte	-128 - 127
Short	-32768 - 32767
Int	-2147483648 - 2147483647
Long	-9223372036854775808 - 9223372036854775807

Unsigned Integral	Ranges
Byte	0 - 255
Ushort	0 - 65535
Uint	0 - 4294967295
Ulong	0 - 18446744073709551615

$\begin{tabular}{ll} Value Types \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types\#built-in-value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types\#built-in-value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types\#built-in-value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types#built-in-value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types} \\ \underline{ thtps://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/value-types/builtin-types/value-types/builtin-types$

Unicode Characters	Range
char	0 - 65535

boolean	Value
bool	true and false (NOT 0/1)

IEEE binary floating-point	values
float	Approx. 1.5 * 10^-45 - 3.4 * 10^38 with precision of 7 digits.
double	Approx. 5.0 * 10^{-324} - 1.7×10^{308} with precision of 15-16 digits.

High-precision decimal floating-point	Values
decimal	1.0 * 10^-28 - approx. 7.9 * 10^28 with 28-29 significant digits

Value Types – Enum

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/enum

An **enum** is a **value** type defined by a set of named constants of the underlying integral numeric type.

To define an enumeration type (*enum*), use the *enum* keyword and specify the names of the *enum* members.

There exist explicit conversions between the **enum** type and its underlying **integral** type. If you cast an **enum** value to its underlying type, the result is the associated integral value of an **enum** member.

Enums are immutable.

```
public enum Season
    Spring,
    Summer,
    Autumn,
   Winter
public class EnumConversionExample
    public static void Main()
        Season a = Season.Autumn;
        Console.WriteLine($"Integral value of {a} is {(int)a}");
                               // output: Integral value of Autumn is 2
        var b = (Season)1;
        Console.WriteLine(b); // output: Summer
        var c = (Season)4;
        Console.WriteLine(c); // output: 4
```

Value Types – Struct

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/struct

A structure type (struct) is a value type that can encapsulate data and related functionality.

Use the **struct** keyword to define a structure **type**. Structure **types** are typically used to design small datacentric **types** that provide little or no behavior.

```
public struct Coords
    public Coords(double x, double y)
       X = x;
        Y = y;
    public double X { get; }
    public double Y { get; }
    public override string ToString() => $"({X}, {Y})";
```

Nullable Value Types

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/nullable-value-types

Reference Type – Class

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/keywords/class

Classes are declared using the keyword *class*. A class can declare class fields, constructors, and methods.

```
class Child
   private int age;
   private string name;
   public Child()
       name = "N/A";
   public Child(string name, int age)
       this.name = name;
       this.age = age;
   // Printing method:
   public void PrintChild()
       Console.WriteLine("{0}, {1} years old.", name, age);
```

Reference Type – Interface

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/keywords/interface

An *interface* contains definitions for a group of <u>related</u> functionalities that a non-abstract *class* or a *struct* must implement.

An *interface* defines a "contract". Any *class* or *struct* that implements that contract agrees to provide an implementation of the members defined in the *interface*.

```
interface ISampleInterface
   void SampleMethod();
class ImplementationClass : ISampleInterface
   // Explicit interface member implementation:
    void ISampleInterface.SampleMethod()
        // Method implementation.
   static void Main()
        // Declare an interface instance.
        ISampleInterface obj = new ImplementationClass();
        // Call the member.
        obj.SampleMethod();
```

Reference Type – Delegate

https://docs.microsoft.com/en-us/dotnet/csharp/tour-of-csharp/delegates https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/reference-types

A *delegate type* represents references to methods. Delegates make it possible to treat methods as entities that can be assigned to variables and passed as parameters. Delegates are similar to function pointers in other programming languages. Unlike function pointers, delegates are object-oriented and typesafe.

```
using System;
delegate double Function(double x);
class Multiplier
    double factor;
    public Multiplier(double factor)
        this.factor = factor;
    public double Multiply(double x)
        return x * factor;
class DelegateExample
   static double Square(double x)
        return x * x;
    static double[] Apply(double[] a, Function f)
        double[] result = new double[a.Length];
        for (int i = 0; i < a.Length; i++) result[i] = f(a[i]);</pre>
        return result;
   static void Main()
        double[] a = {0.0, 0.5, 1.0};
        double[] squares = Apply(a, Square);
        double[] sines = Apply(a, Math.Sin);
        Multiplier m = new Multiplier(2.0);
        double[] doubles = Apply(a, m.Multiply);
```

Reference Type – Object

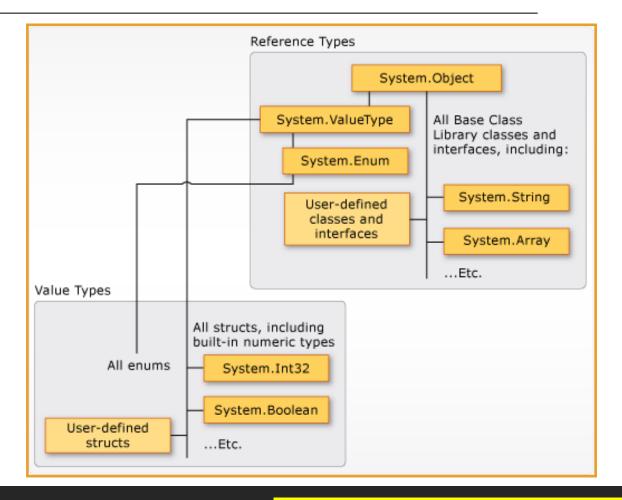

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/reference-types

In C#'s *Unified Type System (UTS)*, all *types* inherit (directly or indirectly) from *System.Object*.

You can assign values of any *type* to variables of *type Object*.

Any *Object* variable can be assigned to its default value using *null*.

When a variable of a value *type* is converted to *Object*, it is <u>boxed*</u>. When a variable of *type Object* is converted to a value *type*, it is <u>unboxed*</u>.

Reference Type – String

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/reference-types

The **string type** represents a sequence of zero or more Unicode characters. **string** is an alias for <u>System.String</u>.

The addition operator '+' and the equality operators '==' and '!=' are defined to concatenate and compare the <u>values</u> of **string objects** (not the references). Strings are *immutable*, meaning the contents of a string object cannot be changed after the object is created, although the syntax makes it appear as if you can.

This example displays "True" and then "False" because the content of the strings are equivalent. a and b do not refer to the same string instance.

```
string a = "hello";
string b = "h";
// Append to contents of 'b'
b += "ello";
Console.WriteLine(a == b); // True
Console.WriteLine(object.ReferenceEquals(a, b));
```

Reference Type – String

https://docs.microsoft.com/en-us/dotnet/csharp/language-reference/builtin-types/reference-types

The [] operator can be used for <u>readonly</u> access to individual characters of a string or iterating over them in a loop. Index values start at 0 and must be less than the length of the string.

```
string str = "test";
char x = str[2]; // x = 's';
```

```
string str = "test";

for (int i = 0; i < str.Length; i++)
{
   Console.Write(str[i] + " ");
}
// Output: t e s t</pre>
```
